# FISHERIES CATCH RECONSTRUCTION OF THE WESTERN ATLANTIC FRENCH ARCHIPELAGO OF Saint Pierre Et Miquelon, 1950-20 10 

Elise Bultel and Kyrstn Zylich<br>${ }^{\text {a }}$ Sea Around Us Project, Fisheries Centre, University of British Columbia, 2202 Main Mall, Vancouver, BC, V6T 174, Canada<br>elise.bultel@gmail.com ; k.zylich@fisheries.ubc.ca

#### Abstract

A catch reconstruction of the marine fisheries catch data for Saint Pierre et Miquelon, a small French archipelago off the coast of Newfoundland, Canada, within the northwest Atlantic (FAO Area 21) was performed from 1950 to 2010. The reconstructed catches, including estimates of unreported catches and discards, amounted to 11 million t , which is 2.9 times the 3.8 million $t$ reported by FAO and NAFO on behalf of Saint Pierre et Miquelon and the French mainland. Only 3\% of this catch was deemed to be taken from inside the EEZ of Saint Pierre et Miquelon. On average, discards accounted for $65 \%$ of the total catch, and fishing sectors as defined by the Sea Around Us were represented as follows: industrial (98\%), artisanal (1.7\%), recreational ( $<1 \%$ ) and subsistence ( $\ll 1 \%$ ). Overall, the French catch for the 1950-2010 period in the archipelago was dominated taxonomically by Gadidae (33\%), Pleuronectidae (32\%), Rajidae (8\%) and Perciformes (5\%).

## INTRODUCTION

The archipelago of Saint-Pierre and Miquelon (SPM) is composed of three main islands: Saint-Pierre, Miquelon and Langlade, the two latest being linked by a sand isthmus (Fig. 1). Being a French 'overseas collectivity', the archipelago is located 25 km south of Newfoundland, Canada, and west of the Grand Banks, famous for their Atlantic cod (Gadus morhua) population, once one of the world's richest fishery resources (Hamilton and Butler 2001). SPM became French in 1815 through the Traité de Paris (Rallier du Baty 1927). The SPM's EEZ, declared in 1992 after decades of negotiations (United Nations 2009), covers around $12,300 \mathrm{~km}^{2}$ of mostly continental shelf (http://www.seaaroundus.org), and is completely surrounded by the Canadian EEZ (Fig. 1).

Fishing and fish-processing have been the main economic activities in $\mathrm{SPM}^{1,2}$ and the sector involved in the processing of fishery products are reported to consist of four businesses: Interpêche, which used to be the only processing company, right after SPEC which initiated an industrial fishery for cod (Gadus morhua) in the 1950s and went bankrupt in the 1970s (Eynaud 1986); Les Nouvelles Pêcheries, which processes snow crab (Chionoecetes opilio) sent to the United States together with lumpfish (Cyclopterus lumpus) and whelk (Buccinum undatum); Pêcheries Paturel, which deals with fresh-pack handling of fish, crab, lumpfish eggs, as well as smoked cod, salmon (Salmo salar), shark and scallops; and Société nouvelle des pêches de Miquelon (SNPM), which specializes in salted cod and has recently invested in scallop farming2.

French fishers started to establish themselves during the $15^{\text {th }}$ century close to the Grand Banks, attracted by abundant fish resources in these waters (De Loture 1949). During the 16 ${ }^{\text {th }}$ century, French vessels fished in the area around Gaspé Peninsula, Nova Sootia, Cap-Breton Island, Newfoundland banks and coasts, and Labrador. After repeated conflicts and wars with England, a succession of treaties led to the disappearance of French-controlled territories in Canada - except for SPM - and increasing restrictions for French vessels operating along the "French shore" of Newfoundland. During the $19^{\text {th }}$ century, further reductions of the fishing area accessible to French vessels along the coast of Canada created a movement towards Iceland and Greenland, where catches were high, but decreased

[^0]from 1925 onwards. Until 1938, Greenland catches compensated for this. Fishing stopped during WWII, and only a few vessels returned to cod fishing after the war, before this fishery disappeared (Hersart De La Villemarqué 1995; Melnychuck and Guénette 2001).

As technology and effort increased after WWII, Atlantic cod came under higher pressure from industrialized trawler fleets and despite Canada's 1976 declaration of a 200-mile EEZ-equivalent zone, which reduced fishing by foreign fleets, the cod biomass fell to one percent of its earlier level and the government declared a moratorium on cod fishing in 1992 (Hamilton and Butler 2001). Since 1994, Canada and France have agreed to work cooperatively on stock management and conservation for the 3PS and 4VS NAFO divisions shared by the two countries ${ }^{3}$.

Our aim with this report is to reconstruct total marine fishery removals for the SPM fleet (within and outside the French EEZ around SPM) from 1950-2010 in order to improve the baseline used for assessing changes in the SPM fisheries (and thus to contribute to improving their management), and to ensure that SPM is included when the global reconstructed catch of the world fisheries is estimated.

## Methods

Baseline
French reported landings in SPM were available through both FAO and NAFO, i.e., the North Atlantic Fisheries Organization, a Regional Fishery Management Organization (Cullis-Suzuki and Pauly 2010). FAO data encompassed the 1950-2010 period, whereas NAFO data started only in 1960. For the overlap period, however, the two datasets were very similar, with the FAO catches being slightly higher ( $2 \%$ on average). However, NAFO data were spatialized, so we decided to use them as our baseline from 1960 to 2010 and to use the FAO data for 1950 to 1959. However, NAFO data did not include catches managed by other fisheries bodies, including ICCAT (International Commission for the Conservation of Atlantic Tunas) and NASCO (North Atlantic Salmon Conservation Organization) data. A few catches were reported as 'Unknown' concerning the NAFO Divisions (i.e., 221 t among three taxa); these catches were allocated to the area where most of the catch of the related taxon originated. Some of the taxa ( 15 of 40) would not have equivalents in the two datasets; but from 1950 to 1969, the taxa reported were the same in the two datasets. In order to spatialize the FAO catch, we calculated the NAFO 5 -year division allocation average, from 1960 to 1964, for the eight taxa reported to FAO and applied them to the FAO yearly catch per taxon for 1950 to 1959.

For the years where the difference in catches between the two datasets was higher than 500 t (i.e., 2004, 2005, 2007, 2009 and 2010), we used the FAO catches for the taxa that were missing or underreported in the NAFO data for the same years (Table 1). The NAFO spatial allocation percentages were kept and applied to FAO catches when NAFO catches were only underreported, otherwise NAFO percentages from previous and following years were interpolated. When no interpolation was possible, we applied the most recent allocation proportions.

[^1]| Table 1. NAFO taxa whose catch were replaced by | FAO catch (ns | $=$ not specified ) |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Taxa | 2004 | 2005 | 2007 | 2009 | 2010 |
| Atlantic Cod | X | X | X | X | X |
| Atlantic Redfishes (ns) |  |  | X | X | X |
| Haddock |  |  | X |  |  |
| Lumpfish (lumpsucker) | X | X | X |  |  |
| Marine Molluscs (ns) |  | X | X |  |  |
| Pollock (saithe) | X | X | X |  |  |
| Queen Crab |  | X | X | X | X |
| Scallops (ns) | X | X | X |  |  |
| Skates (ns) |  | X |  |  | X |
| Witch Flounder |  |  | X | X | X |
| Yellowtail Flounder |  | X |  |  |  |

The SPM's EEZ overlaps with the 3PS and 4VS NAFO areas and represents $10.2 \%$ and $0.8 \%$ of their surface, respectively. Thus, in the absence of a better alternative, the catches reported in these areas were allocated to the EEZ using the same percentages and the remaining was allocated outside of it.

French catch from the mainland's vessels occurring in FAO's Area 21 were also considered. FAO and NAFO datasets were similar for the 1960-2010 period except for four years where the NAFO data were 1 to $9 \%$ higher than the FAO data. However, we used the NAFO data in order to benefit from the geographical catch allocation. Since catch data were not available from 1950 to 1959, as well as for 1989 and 1990, we used the FAO data instead for those years. The 1960 spatial allocation per taxon was applied to the FAO catches from 1950 to 1959. Moreover, we interpolated the spatial allocation per taxon percentages between 1988 and 1991 and applied them to the catches from 1989 and 1990. However, when no data were reported in 1991, we used the 1988 spatial allocation per taxon. Catches coming from the NAFO areas 4VS and 3PS were applied the same percentages than mentioned previously to allocate them within and outside the SPM's EEZ. The others were considered outside the SPM's EEZ.

## Sector allocation

In the early 1950s, the fishing sector in SPM was mostly artisanal, targeting cod and practiced almost exclusively with hand lines using motorized doris (Ancellin 1955). These operations took place within a radius of a few nautical mile around the islands, i.e., inside the current EEZ.

The introduction of industrial vessels (i.e., trawlers) occurred in 1952 and matched the fall of the artisanal fishing company (Eynaud 1986). Thus, prior to 1952, it can be assumed that there was no industrial catch. The proportions of industrial versus artisanal landings for cods were estimated with data reported in Eynaud (1986) for the years 1960, 1970 and 1980. Also, industrial and traditional catch (all species included) were available for 20072 and were used to calculate the industrial/ artisanal ratio. For the missing years, these ratios were interpolated from the aforementioned anchor points, except from 2008 to 2010 , for which we used the 2007 ratio. Then we applied the ratio series to the catch present in the baseline. The catches of vessels from the French mainland were considered exclusively industrial.

## Unreported catch

SPM's fishery is mostly focused on cod, but evidence exists that the handline cod fishery depends on some other species used as bait for the cod fishery, notably mussel, softshell clam, capelin, squid, mackerel and herring, sand eel, waved welk, great scallop, deadlet anemone and northern propeller
clam (Rallier du Baty 1927; De Loture 1949), and that the quantities necessary are enormous (Rallier du Baty 1927). These species are unlikely to have been reported since they were not landed' but used directly for a particular fishery. Furthermore, they are not reported in the earlier years and the miscellaneous fish category contains landings too low to make up for the amount needed. Indeed, for one day of fishing, 18 kg of bait are needed for one boat (Dumont and Provost 2008). Given that the cod season lasted six months, usually from May through October (i.e., 184 days), and that the number of doris was available from 1950 to 1985 (Eynaud 1986), we were able to estimate the respective tonnages for this time period. For the 1986-2010 period, we assumed that the artisanal sector of the SPM fishery compensated for the decline in the catch of the industrial sector (mostly due to the cod stock collapse and subsequent moratorium) and used the same number of doris reported for 1985. This is consistent with the number of doris reported for 1996 by the French Senate ${ }^{4}$.The unreported catch allocation was done equally among the 11 taxa listed above and the catch was allocated exclusively to the SPM EEZ since it was taken by artisanal fleets only.

## Discards

No discards were applied to artisanal catches, as no evidence of discarding by artisanal fishers was found. However, trawlers were reported to discard $2 / 3$ of their catch (De Loture 1949), therefore we multiplied the reported industrial catch by two in order to obtain the related discards. American plaice (Hippoglossoides platessoides) was reported to constitute a major bycatch of trawlers targeting cod (Anon. 1976). Other species, for which fishers would have no interest in retaining, were reported to occur on the banks, such as halibut (Hippoglossus hippoglossus), silver hake (Merluccius bilinearis), tusk (Brosme brosme), angler (Lophius piscatorius), golden redfish (Sebastes norvegicus), Atlantic wolffish (Anarhichas lupus), herring (Clupea harengus), capelin (Mallotus viillosus), American sand lance (Ammodytes americanus), mackerel (Scomber scombrus), witch flounder and brill (Glyptocephalus cynoglossus, Scophthalmus rhombus), as well as rays (Malacoraja senta, Raja eglanteria, and Leucoraja erinacea) (Rallier du Baty 1927). Therefore, we allocated $40 \%$ of the discards to the American plaice and 4\% to each of the 15 other species listed above.

## Recreational catch

Recreational fishing plays an important role in Saint-Pierre and Miquelon and recreational boats are reported to be especially interested in lobster fishing2. Evidence of a recreational fishery for Atlantic salmon was also found and catches were available from 1990-2010 (Herlé 2010). We assumed the fishery started in 1987, together with the legislation, and that the catches from 1987 to 1989 were equal to those of 1990. As we could not find information on the beginning of the lobster recreational fishery, it was assumed to have started in 1987 as well, and, as the reported catch seemed to be low, we estimated the recreational catch to match the annual average of reported catch from 1987 to 2010 (i.e., 1 t •year ${ }^{11}$ ).

## Subsistence catch

The main food resources for the inhabitants of Miquelon island in the late 1930s were reported to be gardening, farming and hunting (Rallier du Baty 1927). However, with such a small land and the main activity of the archipelago being directed towards the sea, it seems likely that SPM's inhabitants would have relied on marine resources for food. Indeed, in winter, people from Saint-Pierre would fish off the coast of the archipelago for subsistence (Moselli 1923). According to Dumont and Provost (2008), capelin's contribution to family subsistence in the North Coast area is incontestable and was used for human (and dog) consumption, as well as land fertilizer in vegetable gardens. Therefore, we assumed the capelin catch for subsistence would be half the amount needed for bait per year. As a way to verify if our assumption was reasonable we calculated a yearly per capita rate, which, even if quite low (6 $\mathrm{kg} \cdot \mathrm{person}{ }^{-1}$.year ${ }^{11}$ in 1950s) and declining over time, made sense in the historical context of the archipelago.

[^2]
## Results

Data reported to FAO on behalf of SPM were well documented and representative of the species found in the literature of the area.

## Within the SPMEEZ

Artisanal
Artisanal landings amounted to just over 3,000 t•year ${ }^{1}$ in the early 1950s and increased rapidly to $6,600 \mathrm{t}$ in 1957 before they gradually decreased to reach a minimum of 1,300 t in 1974 (Appendix 1; Fig. 2a). Then, the catch increased again and peaked twice to 7,000 and 7,800 t in 1987 and 1991, respectively. In 1993, the catches dropped to just under 200 t , then increased to peak in 2000 at 2,800 $t$ and then averaged 1,800 $t \cdot$ year $^{1}$ for the rest of the time period.

The taxa most represented in the artisanal landings were Gadidae (69\%), Pleuronectidae (9\%), Sebastidae (6\%) and Bivalves (3\%). 23 other taxa constituted the $13 \%$ remaining.

## Industrial

Industrial landings within the EEZ averaged 350 t.year ${ }^{-1}$ in the 1950s, then peaked at 1,500 tin 1961 and oscillated around 500 t -year ${ }^{1}$ until 1978 (Appendix 1; Fig. 2a). The catches then peaked at 3,000 t in 1986 and dropped abruptly to 18 t in 1993. An increase followed this event and the industrial landings reached almost 400 t in 2000 but then decreased to their mid-1990s level by 2010.

Most of the industrial landings were represented by Gadidae (85\%), Pleuronectidae and Sebastidae ( $4 \%$ each), as well as Rajidae and Teuthida ( $3 \%$ and $2 \%$, respectively). The 20 other taxa accounted for $3 \%$ of the catch.

Industrial discards followed exactly the same trend as they were proportional to industrial landings and amounted to almost 74,500 t. However, they were mostly composed of Pleuronectidae (48\%), Rajidae (12\%) and Perciformes (8\%). The 32\% remaining consisted in 8 other taxa.

## Recreational

Catches estimated for the recreational sector started in 1987 at about 730 t and oscillated throughout the study period, reaching a minimum of 450 t in 1995 and a maximum of 1,800 t in 2008 (Appendix 1; Fig. 2a). They were almost exclusively composed of Atlantic salmon (99.9\%).

## Subsistence

Subsistence catches averaged 27 t •year ${ }^{-1}$ in the early 1950s and then decreased to 4 t in 1984 where it stayed stable until 2010 (Appendix 1; Fig. 2a). They were composed of capelin only (Osmeridae).

## Outside the SPM EEZ

Industrial reported catches and discards
Industrial landings outside the EEZ started at 133,000 t in 1950 and oscillated until 1968 where they peaked at 174,000 t(Appendix 2). Then, they dropped rapidly and reached 40,000 t-year ${ }^{-1}$ in the early to mid-1970s before peaking at 48,000 tin 1986. In 1993, the catch was down to 160 t , peaked in 1998 at 3,500 t.year ${ }^{-1}$ and stabilized around 2,000 t.year ${ }^{-1}$ in the 2000 s .

Gadidae composed most of the industrial reported catches (96\%) and the remaining catches were represented by 25 other taxa.

Industrial discards outside the EEZ followed the same trend than the industrial landings and made up 7.2 million $t$ over the whole period. The taxonomic composition was the same than the one for the industrial discards within the EEZ.

Overall, Pleuronectidae and Gadidae constituted most of the industrial catch outside of the EEZ with $32 \%$ each, followed by Rajidae ( $8 \%$ ) and Perciformes (5\%; Appendix 4). 24 other taxa made up the remaining $22 \%$.

## DISCUSSION

This study is an attempt to estimate the total French catches taken in and near the (French) EEZ of SPM from 1950 to 2010 using various studies and information. The reconstructed catch estimated (inside and outside the EEZ) is 2.9 times the official data (i.e., 11.1 million t vs 3.8 million t ), a significant discrepancy which reveals that some sectors/ catch components are barely monitored (for the catch within the EEZ the discrepancy is only 1.5 times). Of the total reconstructed catch, the unreported artisanal catches represented $0.1 \%$, unreported industrial catches (discards only) $65 \%$, recreational catches $0.2 \%$, and subsistence catches $0.01 \%$. The reported landings represented $34 \%$ of the catch. We did not attempt to estimate any potential under- or un-reported industrial catches.

French catches within and outside the EEZ showed two different trends. Within the EEZ, the catches increased from 1950 to 1960, then decreased until 1975 before reaching their higher catches in the late 1980s (Fig. 2a). Indeed, the introduction of a new type of trawler (i.e., pêche arrière) and the increase of fishing effort led to higher catches (Anon. 1976). Catches dropped suddenly in the early 1990s, due to both the EEZ inception and cod moratorium, before reaching catch levels lower than those from the early 1950s. However, outside of the EEZ, the catches oscillated around $300,000 \mathrm{t} \cdot$ year ${ }^{1}$ and peaked in 1968 before dropping and, despite an increasing event in 1986, reached only a few thousand tonnes per year in the 2000s.

In both cases, the increase in catch occurring in the 1950s can be explained by the fact that, after WWII, industrial techniques took over artisanal fishing. Indeed, the number of sailboats (baited hooks) decreased, whereas the number of trawlers increased, which was due to the large difference in yield (De Loture 1949).

This intensive fishing led to the exhaustion of fish stocks (Forest et al. 1979), even outside of the 3PS division, where yields have declined by $60 \%$ (Anon. 1976). Similarly, the decline of haddock in the 1960s is explained by overfishing by St-Pierre trawlers, but mostly Newfoundland and Nova Scotia trawlers (Anon. 1976). However, it seems that, in addition to the collapse of the cod stocks, the decline of the French cod fishery is also due to a reduction of demand by the French mainland population for this particular species (Hersart De La Villemarqué 1995; Melnychuck and Guénette 2001).

Transitions in terms of taxonomic composition have occurred in the French catch in Area 21, as well as in the SPM EEZ. Gadidae, which used to make up most of the catch, represent only $29 \%$ in the 2000s, whereas Salmonidae and marine crustaceans catch, which were not significant prior to this decade, make up $31 \%$ and $6 \%$ respectively (Fig. 2b) (Appendix 3). This transition from groundfish to crustaceans was also reported in Newfoundland by Hamilton and Butler (2001).

But overall, even if catch composition has varied over time, major taxa removals estimated in our reconstruction are similar to those reported in the late 1970s (i.e., Gadidae, Pleuronectidae and Sebastidae) (Forest et al. 1979).

It seems that both artisanal and industrial French fisheries have declined over the years in the SPM area (Eynaud 1986; Hersart De La Villemarqué 1995; Melnychuck and Guénette 2001) and that the recreational sector has gradually become important, representing 56\% of the total catch in 2010 (Fig. 2a).

We believe that our reconstructed catch estimates for marine fisheries in FAO Area 21 provide a more comprehensive, yet conservative, baseline of total fishery removals for the 1950-2010 period. We hope that these preliminary estimates will be improved and that they will serve as a basis of future management decisions accounting for all sectors, and therefore reducing the impact we have on marine resources.
