ABSTRACT

Total marine fisheries catches were estimated for France in the Mediterranean Sea for the 1950-2010 time-period using a catch reconstruction approach, which included best available data on catches of the industrial, artisanal, recreational, and subsistence sectors, as well as discards. The total reconstructed catch for the 1950-2010 time period exceeded 4 million tonnes, which is 2.1 times higher than the 1.9 million tonnes officially reported to the United Nations Food and Agriculture Organization (FAO). Just under 3.9 million tonnes were estimated to be caught in the French Mediterranean EEZ area. Major landed taxa were Clupeidae (21%), Scombridae (11%), Sparidae (6%), Engraulidae (5%), Mugilidae (5%) and Octopodidae (5%). The industrial and artisanal sectors were the most prominent, with 58% and 34% of the total catch, respectively, with unreported catches representing 52% of the total catch.

INTRODUCTION

The French Mediterranean coast hosts nearly three million inhabitants, with a density five times higher than the rest of France's mainland. Coastal settlement increased rapidly during the 1960-1975 period, and the demography has been almost stable over the last decade (Anon. 2009). The Gulf of Lions, which corresponds to the United Nations Food and Agriculture Organization's (FAO) Division 37.1.2, extends from the border with Spain in the south to the Italian border in the east (Fig. 1). The western part of the Gulf of Lions is characterized by a wide continental shelf with a mild slope, contrary to the eastern part which has a narrow to non-existent shelf area. The Division 37.1.2 roughly overlaps with the French Mediterranean Exclusive Economic Zone (EEZ),¹ which spans nearly 90,000 km² and has an Inshore Fishing Area² of around 16,000 km² (www.seaaroundus.org). Unlike its Atlantic counterpart – declared in 1972 – the French Mediterranean EEZ was only declared in 2012.³

At the national level, the *Direction des Pêches Maritimes et de l'Aquaculture* (DPMA) coordinates the policies resulting from European and international authorities/conventions (e.g., United Nations Convention on the Law of the Sea (United Nations 1994), United Nations Agreement on Straddling and Highly Migratory Fish Stock (United Nations 1995) responsible for fisheries resource management. In the French Mediterranean, some commercial fish stock management also depend on two Regional Fisheries Management Organisations (RFMO), which are the General Fisheries Council for the Mediterranean (GFCM) and the International Commission for the Conservation of Atlantic Tunas (ICCAT), both in charge of fisheries and tuna conservation. However, artisanal coastal fisheries of the French Mediterranean have been self-managed by cooperative organizations called '*Prud'homies*' for hundreds of years (Templier 1986). In 2012, there were 29 of them. These cooperatives are entrusted with ensuring

¹ Corsica, which was reconstructed in a separate report (Le Manach *et al.* 2011), does not belong to the Gulf of Lions and is not included in the present study.

² The Inshore Fishing Area (IFA) represents the area between the shoreline and either 200 m depth or 50 km distance from shore, whichever comes first (Chuenpagdee *et al.* 2006).

³ Declared on October 14, 2012. See www.legifrance.gouv.fr/affichTexte.do?cidTexte=JORFTEXT000026483528

the best fishing opportunities for its members, i.e., all artisanal fishers, who in turn gain access rights. They manage fishing communities by creating local fishing regulations to ensure sustainable use of a specific territory, help initiate marine protected areas along with scientists, and also self-police their waters when necessary (Decugis 2008). They have traditionally been responsible for, e.g., regulating seasonal closures, restricting gear types, controlling fleet sizes, and setting restrictions for commercial species, although they lack recognition from regional, national and European authorities (Templier 2013).

Commercial fisheries are characterised by coastal, artisanal activities (Farrugio 1991). They include a large number of boats and gear types, and spread all along the coast, which make them difficult to define (Guillou *et al.* 2002). However, fisheries types in the French Mediterranean have evolved over time and trends have emerged. In the 1960s, bottom trawl catches were reported to increase before they dropped, despite a substantial increase in fishing effort (Bonnet 1973). Before 1960, small pelagic catches (mostly Clupeidae and Engraulidae) were reported to be quite low but seem to have increased until the late 1970s, together with the use of light attraction devices called '*lamparos*' and the introduction of the pelagic trawl in 1977 (Pichot *et al.* 1978; Oliver 1983). Having been authorised in 1932, the number of purse seiners diminished considerably after 1977 (Beucher 2008). Despite an increasing fishing effort, pelagic fish catches have stabilized and then decreased, mostly due to difficulties in marketing some species (Pichot *et al.* 1978). However, based on official figures, it is thought that Clupeidae and Engraulidae (along with Tunnini) currently make up most of the catch in the French Mediterranean (Le Guilloux and Pauly 2010).

Artisanal fisheries in the French Mediterranean are known to be grossly unreported (Farrugio and Le Corre 1991; Guillou *et al.* 2002; Le Guilloux and Pauly 2010), and the national data do not include discards, recreational or subsistence catches.

Based on a concept developed by Pauly (1998) and methods developed and implemented worldwide by Zeller *et al.* (2007), Zeller and Harper (2009), Harper and Zeller (2012), and Harper *et al.* (2012), this report aims to reconstruct total marine fishery removals for the French Mediterranean Sea fleet (within and outside the French EEZ) from 1950-2010, which will improve the catch data baseline and, hopefully, inform appropriate management measures.

MATERIALS AND METHODS

French catch within the EEZ

Baseline data

Data published by the United Nations Food and Agriculture Organization (FAO) via FishStat (FAO 2012) software were used as our reported baseline. For the 1970-2010 period, we used the General Fisheries Commission for the Mediterranean (GFCM) dataset, as it contains a spatial resolution that allowed us to distinguish catches from inside and outside the French EEZ, i.e., roughly the 'Gulf of Lions' Division 37.1.2. Due to the lack of finer-scale spatial information in FishStat's 'global capture production' dataset between 1950 and 1969, we considered that the fraction of the catch in the EEZ was on average similar to that of the 1970-2010 period. The remaining data for this early period was therefore considered to be taken outside the EEZ (see 'French catch in the Mediterranean outside the EEZ' section). Note that catches of the 'Tunas' category were excluded prior to these manipulations, since we considered that the data published by ICCAT were of better quality and were therefore used for the baseline of this fishery.

Furthermore, the taxonomic allocation for the earlier years was poor and we therefore improved it. Indeed, only 20 taxonomic groups were reported on average from 1950 to 1977, whereas over 100 were reported in 2010. Thus, we decided to apply the 1978 breakdown (i.e., 57 taxa) to the 1950-1977 period, the rationale being that most taxa were actually fished but not reported prior to their first reported year.

Thus, for each year, the ‘marine fishes nei’ category was disaggregated following the same breakdown percentage as in the 1978 data among the missing taxa. However, the 1978 percentage was then rescaled to 97% in order to keep the ‘marine fishes nei’ portion maintained at 3%. Note that for 1954 and 1956, no ‘marine fishes nei’ catches were reported in the FAO data, so these were calculated by interpolating the ‘marine fishes nei’ percentages between the prior and subsequent years.

Taxonomic allocation according to gear-type

Information on the French fishing fleets in the Mediterranean Sea was available from reports published by the *Système d’Informations Halieutiques* (SIH; Fisheries Information System), which are based on data collected in 2003, and 2006-2011. The different gears reported to be used in the area (i.e., seines, trawls, divers, nets, small dragged gear, other small gear, dredges, and fyke nets [bag-shaped nets opened with rings]) were used to allocate the French Mediterranean catches to different fleets (Lespagnol *et al.* 2005; Leblond *et al.* 2008; Leblond *et al.* 2009). The type of gear likely to catch each taxon was estimated based on the evidence found in the literature (Bonnet 1973; Oliver 1983; FAO 1985; Bauchot 1987; Holthuis 1987; Northridge 1992; Guillou *et al.* 2002; FAO 2003, 2005; Lespagnol *et al.* 2005; Reid *et al.* 2005; Sacchi 2007; Leblond *et al.* 2009; Le Guilloux and Pauly 2010; Leblond *et al.* 2011; Anon. 2013). Then, the catch was allocated equally among the assigned gears for the whole time period. However, a yearly percentage of the three most commonly caught taxa (by weight, i.e., Clupeidae, Engraulidae, and Merlucciidae; 58% of the total catch, respectively) to be allocated to each type of gear likely to target/catch these taxa. For the other taxa, the allocation of the catch to the different gears was considered constant throughout the time-period (Table 1).

Table 1. Anchor points used to allocate catch (%) to gear-type (missing years were linearly interpolated)

Taxa	Years	Nets	Seines	Trawls	Others
Clupeidae	1950-1960 ^a	60	40	-	-
	1961-1965 ^a	40	60	-	-
	1966-1970 ^a	20	80	-	-
	1971-1976 ^a	10	90	-	-
	1980	5	55 ^b	40 ^a	-
	2007-2010	5	18 ^c	78 ^c	-
Engraulidae	1950-1960 ^a	60	40	-	-
	1961-1965 ^a	40	60	-	-
	1966-1970 ^a	20	80	-	-

	1950-1962 ^{b,d}	-	-	80	20
	1975 ^d	20	-	70	10
	2008-2010 ^e	4	-	88	8

^aPichot *et al.* (1978), ^bBeucher (2008), ^cLe Guilloux and Pauly (2010), ^dBonnet (1967), ^eMacher *et al.* (2010)

Sectorial allocation

Once allocated to the different gears, catches were further allocated to either artisanal or industrial sectors by assigning gear types to sector. This second allocation was based on the likelihood that a given gear was used by either one (or a combination) of these two sectors, i.e., by small-scale and/or large-scale fishers (Table 2). A fishing gear was considered to be used by the industrial sector (i.e., large-scale) if it involved an active type of fishing, i.e., was towed from a boat such as a trawler or a seiner (Martín 2012). Thus, a fishing gear was considered to be used by the artisanal sector (i.e., small-scale) if only passive fishing methods were used, e.g., fyke nets and other small gears. For fishing nets, which greatly vary in terms of size and use, we assumed an equal allocation to both sectors.

Table 2: Sectorial allocation (%) based on gear-type

Gear ^a	Artisanal	Industrial
Divers	100	
Fyke nets with rings	100	-
Nets	50	50
Other small gear	100	-
Seines	-	100
Small dragged gear	-	100
Tellin dredges	100	-
Trawls	-	100

^a Based on Leblond et al. (2008), in which seines = 'senneurs', trawls = 'chalutiers', nets = 'fileyeurs', small dragged gear = 'petits arts trainants', other small gear = 'autres petits métiers', tellin dredges = 'telliniens', divers = 'plongeurs' and fyke nets with rings = 'capéchades'.

Unreported catches

Once the reported baseline was established and catches were allocated to gears and sectors, unreported catches were estimated. It is clear from the scientific literature, that only a negligible portion of artisanal catches are sold via official fish auctions, and therefore that most artisanal catches are unreported (Farrugio and Le Corre 1991; Guillou *et al.* 2002; Le Guilloux and Pauly 2010). Furthermore, a recent report underlines that there are financial incentives that may result in under-reporting, as subsidies are given to fishers who do not sell their catch via official auction rooms (Anon. 2010). Therefore, we considered that the reported data accounted for a third of the actual catches for all gears, except for trawlers and seiners, whose catches were likely accurate (Farrugio and Le Corre 1991).

Discards

Discard rates of the various gear-type were collected from two major studies on discards (Kelleher 2005; Vassilopoulou 2012). The trawling discard rate for the French Mediterranean was calculated by averaging the published discard rates for Spanish and Italian bottom trawlers in the Mediterranean Sea, since no information was available specifically for French trawlers. For nets and small dragged gear, the discard rates we used were the same as the Spanish and Italian rates, i.e., 4.13% and 50% respectively. For taxa caught by purse-seiners, the weighted global average discard rate from Kelleher (2005), i.e., 1.6%, was used. When a given gear did not have a specific discard rate (e.g., other types of artisanal gears), the global discard rate suggested in Vassilopoulou (2012), i.e., 4.9%, was used. Finally, divers, dredges, and fyke nets were assumed not to generate any discards, since they are selective fishing activities or allow any potential by-catch to be released in good condition. The scientific literature was then reviewed to allocate the discarded catch of each gear to specific taxonomic groups. A total of 14 taxa were identified (Bauchot 1987; Sacchi 2007; Saïdi and Bradai 2008; Rochet 2011; Anon. 2013), although it is acknowledged that not all discarded taxa have been accounted for. The various taxa were equally distributed for each gear generating discards (Table 3).

Table 3. Taxa allocation (%) for discards depending on gear-type

Gear	Seines	Trawls	Nets	Small dragged gear	Other small gear
Alopiidae	25	7.7	14.3	-	12.5
Argentinidae	-	7.7	-	14.3	-

Triakidae	-	7.7	14.3	-	12.5

Recreational catches

Recreational fishing in France is defined as non-commercial fishing for self- or family-consumption purposes (Pawson *et al.* 2008). It is further defined as a motivated by fun, pleasure or sport, and not by a dependence on fish for food (Gaudin and De Young 2007).

Qualitative information regarding recreational fisheries in the French Mediterranean is scarce. However, this activity is known to be expanding in the Mediterranean area and now plays an important social and economic role, especially with the development of tourism and the enhancement of charter fishing (Gaudin and De Young 2007).

Our reconstruction is mainly based on one set of studies, carried out between 2006 and 2008 (Levrel *et al.* 2009; Levrel 2011; Herfaut *et al.* 2013). These studies are based on a combination of telephone and on-site surveys, in collaboration between a statistical institute and the French Research Institute for the Exploitation of the Sea (IFREMER). A total of 15,000 households were surveyed and their results were scaled up to be representative of the entire territory. Results show that 5.1% of the French population beyond 15 years of age is fishing recreationally, i.e., 2.45 million recreational fishers. An overwhelming majority of these recreational fishers are males between 25 and 64 years of age, who actively fish 13 weeks per year on average. It also appears that most fisher live in the coastal area (Levrel *et al.* 2009).

These studies also illustrate that most fishers feel that the marine resources have been declining over the past years, and that the French recreational fishery has been rapidly expanding for the last 30 years, and is currently catching around 24,000 t·year⁻¹ of fish, as well as 5,200 t·year⁻¹ of shellfish, Crustacea and Cephalopoda (Herfaut *et al.* 2013). Out of these totals, one third are estimated to be caught in the French Mediterranean Sea (Levrel 2011). The most targeted species are seabass (*Dicentrarchus labrax*), Atlantic mackerel (*Scomber scombrus*), and various species of Sparidae and Gadidae (e.g., *Sparus* spp., *Pagrus* spp., *Diplodus* spp., *Pollachius* spp.) (Levrel *et al.* 2009; Levrel 2011; Herfaut *et al.* 2013) although Mediterranean rainbow wrasse (*Coris julus*) and comber (*Serranus cabrilla*) make up most of the recreational catches in terms of sheer abundance in Mediterranean marine protected areas (Font *et al.* 2012). Mugilidae, Blenniidae, Mullidae and Polyprionidae are also reported to be commonly targeted by recreational fishers (Gaudin and De Young 2007).

Based on this information, we considered that the recreational sector truly started to expand in 1976 (i.e., 30 years before the 2006 study), and that the prevalence of recreational fishers in 1976 was 1/4th of that in 2006, i.e., 0.01. We also considered that this ratio had only doubled between 1950 and 1975 (i.e. although

growing, the sector truly started to expand afterwards). Furthermore, we considered that the catch per unit of effort in 1976 was twice that of 2006 (and following years), and stable prior to that, as fishers have been noticing a decline in fish per unit of effort.

For the taxonomic breakdown, we allocated 75% of the total catch to the most targeted families (Moronidae, Scombridae, Sparidae, Serranidae and Gadidae), and equally distributed the remaining percentage among the other families listed in Font *et al.* (2012) and Gaudin and De Young (2007) (i.e., Labridae, Carangidae, Scorpaenidae, Mugilidae, Mullidae, Blenniidae, Polyprionidae), as well as a 'marine fishes' category.

For the non-fish catch, we allocated 5% to Echinodermata, i.e., sea urchins (Nadaud 1955) and the proportions given by Levrel (2011) to the remaining 95%, i.e., Bivalvia and Gastropoda (36%), marine Crustacea (30%), and Cephalopoda (29%).

Subsistence catches

Subsistence fisheries consist in sharing and consuming caught fish (or other marine resources) directly with the family and kin of the fishers (www.fao.org/fishery/topic/12306/en). Pawson *et al.* (2008) explained that the term subsistence fishing in France is based more on the "cultural" element of traditional fishing activities, and one example of this is the tradition of hand-picking shellfish from beaches, such as the Mediterranean mussel (*Mytilus galloprovincialis*), which has been traditionally harvested from the French Mediterranean coast for millennia. While farms have grown immensely in recent decades, there is still a small public fishery for wild mussels (Prou and Gouletquer 2002).

No data were found regarding subsistence-type or traditional fisheries but we did not want to ignore catches from this sector, as is often the case. Therefore to estimate subsistence catches, it was simply assumed that subsistence catches were of the same amount as our estimated recreational catch amounts from 1950-1959 (i.e., which average of 1,650 t·year⁻¹ for the decade), and then the 1959 value was linearly decreased to one percent of the 1959 value by 1980, as Bivalvia culturing grew in prominence by then. This assumption is justifiable by the fact that France is a rich country and thus it can be assumed that subsistence fishing is marginal. Also, due to the lack of pronounced tides in the Mediterranean, the gleaning of shellfish along its beaches is far more limited than on the French Atlantic coast and it is considered to be very low in the 2000s. Therefore, there is no double accounting with regards to the recreational catch estimated by Herfaut *et al.* (2013).

To allocate these subsistence catches to taxa, we used the same invertebrate breakdown proportions as the recreational sector but added a "marine fishes" group representing 20% and kept Echinodermata at 5%; shellfish (Bivalvia and Gastropoda) at 29%; marine Crustacea at 24%; and Cephalopoda at 22%.

Tunas

The baseline for 'Tunas' (containing mostly Scombridae but also Istiophoridae and Xiphiidae) came from the data published by ICCAT, as their taxonomic resolution was better than the more generic FishStat data. They included catches of Albacore (*Thunnus alalunga*), bigeye tuna (*Thunnus obesus*), Atlantic bluefin tuna (*Thunnus thynnus*), bullet tuna (*Auxis rochei*), Atlantic bonito (*Sarda sarda*), plain bonito (*Orcynopsis unicolor*), little tunny (*Euthynnus alletteratus*), skipjack tuna (*Katsuwonus pelamis*), longbill spearfish (*Tetrapturus pfluegeri*), swordfish (*Xiphias gladius*), wahoo (*Acanthocybium solandri*), yellowfin tuna (*Thunnus albacares*) and tunas nei. ICCAT data - which included some species common with FAO and GFCM data (i.e., Albacore, Atlantic bluefin tuna, Atlantic bonito, little tunny, skipjack tuna, and swordfish) matched the GFCM data except during the 2000s, for which the GFCM tunas catches were higher.

Farrugio and Le Corre (1991) explained that tuna catches were reported for the most part. However, Fonteneau and Fromentin (2009) later reported that since 1996, bluefin catches were under-reported by 30%. Hence, beginning in 1996, we added 30% to the reported bluefin catches to account for this unreported component (ICCAT 2009). The evolution of tuna catches attributed to different gears was also available in the ICCAT data. Since, on average, 99% of the tunas catch was bluefin tuna, their yearly gear allocation was applied to all tuna catches. The gear-related discards were then estimated as previously described in the 'discards' section. However, note that ICCAT data also include sport catches, which were removed from these calculations and reallocated to the 'Other marine fish' previously estimated for the recreational sector.

The sectorial allocation was performed slightly differently than for the artisanal sector: gillnets (nets) and unclassified gear (other small gear) were considered as artisanal, whereas purse seines and trawls were considered as industrial. We further considered that catches of nets and other small gears were exclusively taken in the EEZ (J-M Fromentin, pers. comm., IFREMER), whereas catches of seines and trawls were considered to come exclusively from the EEZ only from 1950 to 1980, and then progressively from outside the EEZ as well before reaching respectively 100% and 50% of catch coming from outside the EEZ by 2000. Between 1981 and 1999 these ratios were linearly interpolated and from 2001 to 2010 the same geographical allocation was kept.

French catch outside the EEZ

As described in the 'Baseline data' section, GFCM data allowed the segregation of catch between 'within' and 'outside' the Division 37.1.2, which we considered to represent the French Mediterranean EEZ. GFCM catches other than in Division 37.1.2 were used for the 1970-2010 period, similarly to the first part of the exercise, we considered that the proportion of the catch taken outside the French EEZ for the 1950-1969 was similar to that of 1970-2010, in the absence of a spatial breakdown in the FishStat database for this period. Unlike for the catch inside the EEZ, we did not perform a taxonomic breakdown for the earlier years. The gear allocation was also performed differently than for the Gulf of Lions catches. Indeed, we divided the catch among only three gears (i.e., seines, trawls, and nets), as they were the only gears likely to be active that far away from the French coasts. Their respective percentages were estimated by using results from Le Guilloux and Pauly (2010), who classified gear by boat power, allowing them to go further offshore. As only seines and nets were represented in classes where High Seas boats were dominant, and as trawls were represented in a class where coastal and high sea activities were mixed, we took into account their respective importance in each class and used the following percentages: seines (70%), trawls (10%) and nets (20%). Furthermore, all catches were considered to be industrial (i.e., artisanal fishing is restricted to near-shore areas). Finally, we added the ICCAT tuna estimated to have been caught outside the Gulf of Lions to this baseline.

RESULTS

Inside the EEZ

Industrial catches

Industrial reported catches

Industrial reported catches for the 1950-2010 period amounted to almost 1.3 million tonnes. The industrial and artisanal catches were similar in the 1950s, when they averaged just over 5,200 t-year⁻¹. (Fig. 2a; Appendix 1). Industrial reported catches gradually increased throughout our study period and peaked in the early 1980s, whereby they averaged almost 32,700 t-year⁻¹. They subsequently dropped to nearly 15, 000 t-year⁻¹ in 1996, before reaching again 30,000 t-year⁻¹ by 2000 and finally declined to an average of less than 13,000 t-year⁻¹ during 2008-2010.

The major reported taxonomic groups for the industrial sector were Clupeidae (635,000 t), Engraulidae (183,000 t), Scombridae (119,000 t), Merlucciidae (86,400 t), Sparidae (38,400 t) and Gadidae (25,000 t) with 58 other taxonomic groupings accounting for the remaining 15.8% of catches.

Industrial unreported landings

Industrial unreported catches for the 1950-2010 period amounted to 471,000 t, peaked in 1972 with just over 17,300 t, and averaged 7,700 t·year⁻¹ for the whole period.

The major industrial unreported taxonomic groups for this sector were Clupeidae (80,200 t), Octopodidae (46,300 t), Sparidae (46,000 t), Ostreidae (27,000 t), Elasmobranchii (23,600 t) and Mytilidae (19,900 t), while 52 other taxa accounted for the remaining 48.4% of the catch.

Discards

Discards from the industrial sector were estimated at almost 372,000 t for the entire 1950-2010 period. Discards averaged just over 2,300 t·year⁻¹ throughout the 1950s, gradually increased to a peak of over 12,000 t in 1986, 1992 and 2003, and then gradually declined to average just over 5,100 t·year⁻¹ for 2008-2010.

The main species discarded by the industrial sector throughout the 1950-2010 period were Elasmobranchii (40,800 t), and Mugilidae, Carangidae, Rajidae, Cepolidae, and Argentidae (each at 36,200 t). Eight other taxa accounted for the remaining 40.3% of catch.

Artisanal catches

Artisanal reported catches

Artisanal reported catches for the 1950-2010 period amounted to around 460,000 t. These catches peaked in 1972 (15,900 t) then globally decreased since 1992, and averaged 7,500 t·year⁻¹ for the whole period (Appendix 1; Fig. 2a).

The main taxa caught by the industrial sector were Mugilidae (42,800 t), Clupeidae (40,100 t), Scombridae (39,600 t), Octopodidae (38,600 t), Sparidae (38,400 t), and Gadidae (25,000 t), with 59 other taxa accounting for the remaining 51.2% of catch.

Artisanal unreported catches

Artisanal unreported catches for the 1950-2010 period amounted to over 893,000 t. These catches had a trend similar to that of the reported artisanal catches, and averaged just over 14,600 t·year⁻¹ for the 1950-2010 period.

The major caught taxa reported by the artisanal sector were Mugilidae (85,600 t), Clupeidae (80,200 t), Octopodidae (77,200 t), Sparidae (76,800 t) and Scombridae (53,200 t) with 58 other taxonomic groupings accounting for the remaining 58.2% of catch.

Discards

Discards from the artisanal sector were estimated at just over 40,600 t for the 1950-2010 period, peaking in 1972 at over 1,300 t·year⁻¹ and averaging just under 670 t·year⁻¹ throughout the 1950-2010 period (Appendix 1) (Fig. 2a).

The major groups discarded by the artisanal sector were Triakidae, Squalidae, Carcharhinidae, Alopiidae and Elasmobranchii (5,400 t each), Clupeidae and Rajidae (2,900 t each) and Scyliorhinidae (2,500 t).

Recreational catches

Our estimate of the unreported recreational catches for the 1950-2010 period is 286,000 t. They averaged 1,570 t-year⁻¹ from 1950-1954, and reached an average of 8,980 t-year⁻¹ by 2006. The only reported recreational catch consisted in the ICCAT tuna catch, which only amounted to 730 t.

The recreational catches were distributed by family as follows: Gadidae, Moronidae, Scombridae, Sparidae and Serranidae almost reached 40,600 t, while Blenniidae, Carangidae, Labridae, Mugilidae, Mullidae, Polyprionidae and Scorpaenidae reached over 8,450 t each for the whole period. Seven other taxa accounted for the remaining 8.6%.

Subsistence catches

The estimate of subsistence catches for the Gulf of Lions for the 1950-2010 period reached just over 39,100 t (Fig. 2a) (Appendix 1). Of this amount, marine Crustacea accounted to 9,400 t, Cephalopoda amounted to around 8,600 t, Bivalvia and Gastropoda to nearly 5,700 t, and Echinodermata to almost 2,000 t.

Total reconstructed catch for EEZ

The total reconstructed catch for the French Mediterranean for the 1950-2010 period was 3.85 million tonnes, which is 2.2 times higher than the 1.75 million reported to FAO, i.e., an add-on of roughly 2.1 million tonnes of unreported catches (Appendix 1).

Specifically, the unreported catches mostly consisted of artisanal catches (893,000 t), followed by industrial catches (471,000 t), industrial discards (372,000 t), recreational catches (286,000 t), artisanal discards (40,700 t), and subsistence catch (39,200 t).

Overall, the main species caught in the Gulf of Lions from 1950 to 2010 were Clupeidae (856,000 t), Scombridae (287,000 t), Sparidae (240,000 t), Engraulidae (218,000 t), Mugilidae (199,000 t) and Octopodidae (185,000 t; Fig. 2b; Appendix 3). The remaining 48.5% of total reconstructed catches consisted of 67 other taxa.

Outside the EEZ

GFCM catch reported outside the EEZ were extremely variable throughout the years in terms of total catch and taxonomic composition. They were the most important from the 1970s until the 1990s, with also two peaks in 2002 and 2009 (Appendix 2). However, together with the ICCAT tuna catch allocated outside the EEZ, the total catch outside the EEZ strongly increased from nearly 500 t in 1950 to 11,000 t in 2005, before dropping rapidly to 2,500 t in 2010.

Discards followed the same trend and reached 200 t in 2007 before dropping to around 50 t by 2010 (Appendix 2). Unreported catches consisted of Scombridae and amounted to approximately 2,100 t in 1996 before increasing to 2,900 t in 2007 and decreasing to 470 t by 2010.

Overall, Scombridae and Clupeidae made up 76.5% and 4.5% of the catch, respectively, while 53 other taxa accounted for 21.3% of the total catch outside the French Mediterranean EEZ (Appendix 4).

DISCUSSION

This report is a first attempt to re-estimate the total marine fishery removals for the French Mediterranean Sea, in order to confront national data reported to the FAO from 1950 to 2010 to a more comprehensive baseline derived from independent estimates. The reconstructed catch is more than twice the official data, which highlights the discrepancy between the reported catch and the amount of marine likely actually caught. Of the total reconstructed catch, the unreported artisanal catches, unreported

industrial catches, recreational catches, and subsistence catches represented 44% (2% discards, 42% unreported), 41% (18% discards, 23% unreported), 13%, and 2%, respectively.

This huge disparity between the quality and comprehensiveness of data on artisanal versus industrial fisheries is common throughout the world, as many countries have not even begun to comprehensively account for their artisanal fishing sector. France does monitor this sector, but only partially (Farrugio and Le Corre 1991; Guillou *et al.* 2002; Le Guilloux and Pauly 2010), and it has been demonstrated here that the artisanal sector catch is substantial, representing about half that of the industrial sector in terms of tonnage.

While the *prud'homies* have been successful at managing their resources for centuries, they are no longer able to restrict the access of coastal inshore fishing areas to other sectors such as the recreational and industrial sectors, which is causing increasing tension between sectors and negatively impacting any notion of sustainable management. Overall, the French Mediterranean fisheries show a worrisome trend, with catches declining at a very rapid rate in the last decade. Indeed, the total reconstructed industrial catches declined by a factor of 2.4 between 2000 and 2010, while the total reconstructed artisanal catches declined by a factor of 1.4 during the same period. This trend parallels that of fish stock biomass, which has been shown to have declined by 80% since the industrialization of fisheries (Cardinale *et al.* 2012).

On the other hand, recreational catches by locals did not show the same declining trend, probably because this sector is becoming more popular (i.e., effort increases), which may have masked the average declining catch per unit of effort noticed by many surveyed fishers (Levrel *et al.* 2009). Noteworthy, Herfaut *et al.* (2013) noted that the recreational sector may represent a major part of the total catch for some species, e.g., 100% of the commercial landing of European sea bass, and 19% and 44% for Atlantic mackerel and sea bream, respectively. Compared to Le Goff *et al.* (2012), who reported recreational catch for the whole French mainland in 2011, our estimate of Bivalvia and Crustacea catches seem quite low. However, the most favorable areas for collecting these taxa are mostly located on the Atlantic and English Channel coasts, hence it seems realistic that smaller amounts are collected in the Mediterranean area. It is also important to acknowledge that we did not estimate bycatch and bait catches related to recreational fisheries. However, these could constitute significant amounts and should be monitored (Gaudin and De Young 2007).

Due to the lack of data, it is also important to note that our recreational catch estimates should be improved upon as we did not include any catches taken by tourists. Indeed, since the Mediterranean is a major tourist destination (Garau-Taberner and Manera 2006), it can be expected that the high number of tourists can drive the fishing pressure, directly (i.e., fishing by themselves) or indirectly (i.e., willing to eat fresh fish), and therefore have a consequent impact on the resources, especially during summer months (Trumbic 2005). This is a topic to explore, especially as tourism in the region is expected to double by 2025 (Barceló *et al.* 2011).

Concerning the GFCM catch reported outside of the EEZ, it seems highly unlikely that they dropped from 1000 t in the 1990s to around 20 t in the 2000s with only two punctual high catches in 2002 and 2009. We think that catch data coming from this area are of quite poor quality for this time period but we lacked information to reliably estimate the magnitude of unreported catches.

We believe that our reconstructed catch estimates for the French Mediterranean marine fisheries provide a more comprehensive baseline of total fishery removals for the 1950-2010 period, notably by identifying major discrepancies between the reported catch and independent estimates and anecdotal evidences about all fisheries sectors. We hope that these preliminary estimates will be improved by focusing on the aforementioned weaknesses, and that they will serve as a basis of future management decisions accounting for all sectors, and therefore reducing the impact we have on the marine resources.
